Session 2: Key-Value Stores (kompakt)

Lernziele: Key-Value Paradigma verstehen | Zugriffsmuster & Patterns kennen | Grenzen & Trade-offs bewerten

Rückblick: Was haben wir beim letzten Mal gelernt?

Willkommen zurück! Bevor wir in Key-Value Stores eintauchen, lasst uns kurz rekapitulieren, wo wir letzte Woche geendet haben.

Session 1 Recap

- ✅ **Rohdaten-Formate**: CSV, JSON, YAML, XML
- ✅ **Ad-hoc Analysen**: Programmiersprachen direkt auf CSV
- ✅ **Problem erkannt**: Lineare Suche = $O(n)$ Zeitkomplexität
- ✅ **Inkonsistenzen**: Keine Validierung, keine Integrität

Wir haben gesehen, dass Dateien flexibel sind, aber bei strukturierten Zugriffen schnell an Grenzen stoßen. Heute schauen wir uns an, wie Key-Value Stores dieses Problem lösen.

Zentrale Frage aus: Wie können wir schneller als $O(n)$ auf Daten zugreifen?

Wie dargestellt, benötigen wir linearen Zeitaufwand, um in eine Datei nach einem Eintrag zu suchen zu durchsuchen. Wenn ihr noch nicht wisst, was $O(n)$ bedeutet, keine Sorge – wir werden das gleich im Detail besprechen!

Das Problem: CSV-Suche ist langsam

Nehmen wir eine Produktdatenbank als Beispiel und schauen wir uns an, was passiert, wenn wir ein einzelnes Produkt suchen müssen.

Szenario: Wir haben eine CSV-Datei mit Produkten und wollen Details zu Produkt `P00567` finden.

Eine typische Produkt-CSV mit ID, Name, Kategorie, Preis, Lagerbestand. Nichts Besonderes – aber schauen wir uns die Performance an!

Naive Implementierung: Lineare Suche

```
1  const response = await fetch("https://raw.githubusercontent.com/andre
     -dietrich/Datenbankensysteme-Vorlesung/refs/heads/main/assets/dat
     /products.csv");
```

```
2  const text = await response.text();
3  const rows = Papa.parse(text, { header: true }).data;
4
5  function searchProductById(productId) {
6    const start = performance.now();
7    let found = null;
8
9    // Zeilenweise durchsuchen (O(n)!)
10   for (let i = 0; i < rows.length; i++) {
11     sleep(1); // Simuliere Latenz (I/O, Parsing)
12     if (rows[i].product_id == productId) {
13       found = rows[i];
14       break;
15     }
16   }
17
18   const end = performance.now();
19
20   if (!found) {
21     console.log("❌ Produkt nicht gefunden");
22   } else {
23     console.log("✅ Produkt gefunden:", JSON.stringify(found, null, 2
24   }
25
26   console.log("⏱️  Zeit:", (end - start).toFixed(2), "ms");
27 }
28
29 searchProductById("P00567");
```

```
✅ Produkt gefunden: {
  "product_id": "P00567",
  "name": "Building Blocks Set Max",
  "category": "Toys",
  "brand": "SunnyPlay",
  "price": "46.45",
  "stock": "257",
  "rating": "4.7",
  "created_at": "2025-03-06"
}
⏱️  Zeit: 566.40 ms

}
⏱️  Zeit: 566.80 ms
```

Probiert verschiedene Produkt-IDs aus! Beobachtet: Je weiter hinten das Produkt in der Datei steht, desto länger dauert die Suche. Im schlimmsten Fall müssen wir die gesamte Datei durchsuchen!

Problem: Lineare Suche = $O(n)$ **Zeitkomplexität**

- 1.000 Produkte? Noch ok (~1 Sekunde)
- 1.000.000 Produkte? **Nicht mehr praktikabel (~17 Minuten)**
- **Skalierungsproblem**: Verdoppelung der Daten = Verdoppelung der Suchzeit

Big-O Notation: Kurzer Exkurs

Big-O Notation ist eine mathematische Notation, die verwendet wird, um die Leistung oder Komplexität eines Algorithmus zu beschreiben. Sie konzentriert sich auf das Worst-Case-Szenario und ignoriert Konstanten und niedrigere Ordnungstermine. Aber was bedeutet das konkret?

Alltags-Analogie: Bücher im Regal finden

Stellt euch vor, ihr sucht ein bestimmtes Buch in einem Regal:

- $O(1)$ – **Konstant**: Ihr wisst genau, wo das Buch steht (Position 42). Egal ob 10 oder 10.000 Bücher im Regal – ihr greift direkt zu. **Wie ein Hash-Lookup!**
- $O(\log n)$ – **Logarithmisch**: Die Bücher sind alphabetisch sortiert. Ihr schaut in die Mitte, wisst ob links oder rechts, halbiert wieder – wie beim Telefonbuch. Bei 1.000 Büchern nur ~10 Schritte!
- $O(n)$ – **Linear**: Bücher sind unsortiert. Ihr müsst jedes einzelne Buch durchgehen. 1.000 Bücher = 1.000 Checks im Worst Case. **Wie CSV-Scan!**
- $O(n \log n)$ – **Linearithmisch**: Ihr wollt alle Bücher alphabetisch sortieren (z.B. mit MergeSort). Jedes Buch muss mindestens einmal angefasst werden (n), und dabei werden $\log n$ Vergleichsebenen durchlaufen. Langsamer als $O(n)$, aber viel schneller als $O(n^2)$!
- $O(n^2)$ – **Quadratisch**: Ihr vergleicht jedes Buch mit jedem anderen (z.B. Duplikate finden). Bei 1.000 Büchern = 1.000.000 Vergleiche!

Diese Analogie macht klar: Die Wahl der richtigen Datenstruktur und des richtigen Algorithmus kann den Unterschied zwischen Millisekunden und Stunden ausmachen!

Visualisierung: Wachstum bei steigender Datenmenge

Seht ihr den Unterschied? $O(1)$ bleibt flach – egal wie viele Daten. $O(n^2)$ explodiert förmlich! Das ist der Grund, warum Hash-Tables so wertvoll sind. Bewegt die Maus über die Linien, um die genauen Werte zu sehen!

Die häufigsten Big-O-Klassen im Überblick

Komplexität	Name	Beispiel	100 Elemente	1.00 Element
$O(1)$	Konstant	Hash-Lookup, Array[index]	1 ms	1 m
$O(\log n)$	Logarithmisch	Binäre Suche, Baum-Traversierung	~7 ms	~10 m
$O(n)$	Linear	Array durchsuchen, CSV scannen	100 ms	1
$O(n \log n)$	Linearithmisch	Gute Sortieralgorithmen (Mergesort)	~700 ms	~10
$O(n^2)$	Quadratisch	Nested Loops, Bubble Sort	10 s	~17 mi

Diese Tabelle zeigt: Ab einer bestimmten Datenmenge wird der Algorithmus zum Flaschenhals. $O(n^2)$ ist bei 1 Million Elementen praktisch unbenutzbar!

Konkrete Code-Beispiele

```
// O(1) - Konstant: Direkter Zugriff
const product = db["P00567"];  // Immer gleich schnell!

// O(n) - Linear: Alle Elemente durchgehen
for (let i = 0; i < products.length; i++) {
  if (products[i].id === "P00567") return products[i];
}

// O(log n) - Logarithmisch: Binäre Suche (nur bei sortierten Daten!)
function binarySearch(sortedArray, target) {
  let left = 0, right = sortedArray.length - 1;
  while (left <= right) {
    const mid = Math.floor((left + right) / 2);
    if (sortedArray[mid] === target) return mid;
    if (sortedArray[mid] < target) left = mid + 1;
    else right = mid - 1;
  }
  return -1;
}
```

```
// O(n²) - Quadratisch: Verschachtelte Loops
for (let i = 0; i < products.length; i++) {
  for (let j = 0; j < products.length; j++) {
    // Vergleiche jedes Produkt mit jedem anderen
  }
}
```

Der Code macht den Unterschied deutlich: Ein Hash-Lookup ist eine einzige Zeile. Eine verschachtelte Schleife muss potentiell Millionen von Operationen durchführen!

Merkregel: Je flacher die Kurve, desto besser skaliert der Algorithmus!

- **Gut**: $O(1), O(\log n)$
- **Akzeptabel**: $O(n), O(n \log n)$
- **Problematisch**: $O(n^2), O(2^n), O(n!)$

Big-O Cheat Sheet: https://www.bigocheatsheet.com/

Die Lösung: Hash-basierter Index (Key-Value!)

Jetzt kommt der Aha-Moment: Was wäre, wenn wir die CSV einmal einlesen, aber dann einen Index bauen? Genau das macht ein Key-Value Store!

Optimierte Implementierung: Hash-Lookup

```
1  const response = await fetch("https://raw.githubusercontent.com/andre
     -dietrich/Datenbankensysteme-Vorlesung/refs/heads/main/assets/dat
     /products.csv");
2  const text = await response.text();
3  const rows = Papa.parse(text, { header: true }).data;
4
5  // Index bauen: Key = product_id, Value = komplettes Produkt-Objekt
6  const db = {};
7  rows.forEach((row) => {
8    db[row.product_id] = row;
9  });
10
11 function searchProductById(productId) {
12   const start = performance.now();
13
14   // O(1) Lookup! 🚀
15   sleep(1); // Simuliere minimale Latenz
16   const product = db[productId];
17
18   const end = performance.now();
19
20   if (product !== undefined) {
```

```
    console.log("✅ Produkt gefunden:", JSON.stringify(product, null,
  } else {
    console.log("❌ Produkt nicht gefunden");
  }

  console.log("⏱️  Zeit:", (end - start).toFixed(2), "ms");
}

searchProductById("P00567");
```

```
Identifier 'response' has already been declared
```

Boom! Von mehreren Sekunden auf unter 1 Millisekunde! Der Index macht den Unterschied: Wir zahlen einmal den Preis fürs Einlesen und Indexieren, danach sind alle Lookups blitzschnell.

Performance-Vergleich

Methode	Zeitkomplexität	1.000 Produkte	1.000.000 Produkte
Lineare Suche	$O(n)$	1s	17min
Hash-Lookup	$O(1)$	$< 1\text{ms}$	$< 1\text{ms}$

Das ist die Superkraft von Key-Value: Konstante Zugriffszeit, egal wie viele Daten ihr habt!

Wie funktioniert das intern?

Aber wie kann ein Hash-basierter Index so schnell sein? Die Antwort: Hash-Funktionen! Schauen wir uns an, wie das im Detail funktioniert.

Das Prinzip: Von Key zu Array-Index

Eine Hash-Funktion nimmt einen beliebigen Key (String, Number) und berechnet daraus eine Zahl – den Hash-Code. Diese Zahl wird als Array-Index verwendet. Direkter Array-Zugriff ist $O(1)$!

Schritt-für-Schritt: Einfache Hash-Table Implementation

```
// Vereinfachte Hash-Table (zum Verständnis)
class SimpleHashTable {
  constructor(size = 100) {
    this.buckets = new Array(size);  // Array mit 100 Slots
    this.size = size;
  }

  // Hash-Funktion: String → Number
  hash(key) {
    let hashValue = 0;
    for (let i = 0; i < key.length; i++) {
      hashValue += key.charCodeAt(i);  // ASCII-Wert summieren
    }
    return hashValue % this.size;  // Modulo für Array-Größe
  }

  // SET: Key-Value speichern
  set(key, value) {
```

```
    const index = this.hash(key);
    console.log(`SET "${key}" → Hash: ${index}`);
    this.buckets[index] = { key, value };  // Vereinfacht!
  }

  // GET: Value abrufen
  get(key) {
    const index = this.hash(key);
    console.log(`GET "${key}" → Hash: ${index}`);
    const bucket = this.buckets[index];
    return bucket ? bucket.value : undefined;
  }
}

// Demo
const hashTable = new SimpleHashTable(10);

hashTable.set("P00567", { name: "Laptop", price: 999 });
hashTable.set("P00123", { name: "Mouse", price: 25 });
hashTable.set("P00999", { name: "Keyboard", price: 75 });

console.log("\n--- Lookups ---");
const laptop = hashTable.get("P00567");
console.log("Found:", laptop);

const mouse = hashTable.get("P00123");
console.log("Found:", mouse);

// Nicht vorhanden
const unknown = hashTable.get("P99999");
console.log("Found:", unknown);
```

```
SET "P00567" → Hash: 8
SET "P00123" → Hash: 6
SET "P00999" → Hash: 7

--- Lookups ---
GET "P00567" → Hash: 8
Found: {"name":"Laptop","price":999}
GET "P00123" → Hash: 6
Found: {"name":"Mouse","price":25}
GET "P99999" → Hash: 5
Found: undefined
```

Seht ihr? Die Hash-Funktion berechnet aus dem Key einen Index. Dann greifen wir direkt auf `buckets[index]` zu – $O(1)$! Das ist die Magie hinter Hash-Tables.

Problem: Hash-Kollisionen

Hash-Kollisionen sind unvermeidbar! Die Lösung: Chaining. Jeder Bucket speichert eine Liste von Key-Value-Paaren. Bei einer Kollision durchsuchen wir nur diese kleine Liste – immer noch sehr schnell!

Verbesserte Implementation mit Collision-Handling

```
class HashTableWithChaining {
  constructor(size = 10) {
    this.buckets = new Array(size).fill(null).map(() => []);
    this.size = size;
  }

  hash(key) {
    let hashValue = 0;
    for (let i = 0; i < key.length; i++) {
      hashValue += key.charCodeAt(i);
    }
    return hashValue % this.size;
  }

  set(key, value) {
    const index = this.hash(key);
    const bucket = this.buckets[index];

    // Prüfen ob Key schon existiert (Update)
    for (let i = 0; i < bucket.length; i++) {
      if (bucket[i].key === key) {
```

```
22          bucket[i].value = value;
23          console.log(`UPDATE "${key}" at bucket ${index}`);
24          return;
25        }
26      }
27
28      // Neuer Key → anhängen
29      bucket.push({ key, value });
30      console.log(`INSERT "${key}" at bucket ${index} (chain length: ${
          .length})`);
31    }
32
33    get(key) {
34      const index = this.hash(key);
35      const bucket = this.buckets[index];
36
37      // Bucket durchsuchen
38      for (let i = 0; i < bucket.length; i++) {
39        if (bucket[i].key === key) {
40          console.log(`FOUND "${key}" at bucket ${index}`);
41          return bucket[i].value;
42        }
43      }
44
45      console.log(`NOT FOUND "${key}"`);
46      return undefined;
47    }
48
49    // Debugging: Alle Buckets anzeigen
50    showBuckets() {
51      console.log("\n=== Hash Table Structure ===");
52      for (let i = 0; i < this.size; i++) {
53        if (this.buckets[i].length > 0) {
54          const keys = this.buckets[i].map(item => item.key).join(", ")
55          console.log(`Bucket ${i}: [${keys}]`);
56        }
57      }
58    }
59  }
60
61  // Demo mit Kollisionen
62  const ht = new HashTableWithChaining(5);  // Kleiner = mehr Kollision
63
64  ht.set("P00123", { name: "Mouse", price: 25 });
65  ht.set("P00567", { name: "Laptop", price: 999 });
66  ht.set("P99999", { name: "Monitor", price: 299 });
67  ht.set("P00321", { name: "Keyboard", price: 75 });
68
69  ht.showBuckets();
70
71  console.log("\n=== Lookups ===");
```

```
71 console.log("\n--- Lookups ---");
72 console.log("Mouse:", ht.get("P00123"));
73 console.log("Laptop:", ht.get("P00567"));
74 console.log("Unknown:", ht.get("XXXXX"));
```

```
INSERT "P00123" at bucket 1 (chain length: 1)
INSERT "P00567" at bucket 3 (chain length: 1)
INSERT "P99999" at bucket 0 (chain length: 1)
INSERT "P00321" at bucket 1 (chain length: 2)

=== Hash Table Structure ===
Bucket 0: [P99999]
Bucket 1: [P00123, P00321]
Bucket 3: [P00567]

--- Lookups ---
FOUND "P00123" at bucket 1
Mouse: {"name":"Mouse","price":25}
FOUND "P00567" at bucket 3
Laptop: {"name":"Laptop","price":999}
NOT FOUND "XXXXX"
Unknown: undefined
```

Diese Implementation zeigt: Selbst mit Kollisionen ist der Lookup extrem schnell! Solange die Bucket-Listen kurz bleiben (gute Hash-Funktion + ausreichende Größe), haben wir praktisch $O(1)$.

> **In der Praxis**: JavaScript-Objekte, Redis, Python Dictionaries – alle nutzen Hash-Tables mit ausgeklügelten Hash-Funktionen und automatischer Größenanpassung (Rehashing).

Grenzen von Key-Value Stores

Jetzt kommt der Haken: Key-Value ist perfekt für ID-Lookups, aber was ist mit komplexeren Abfragen?

Szenario: Finde alle Produkte mit Lagerbestand < 10 (Low Stock Alert)

```
1  function filterProductsBy(filter) {
2    const start = performance.now();
3    const results = [];
4
5    // Müssen ALLE Keys durchsuchen! (wieder O(n))
6    for (const productId in db) {
7      sleep(1); // Simuliere Latenz
8      const product = db[productId];
9      if (filter(product)) {
10       results.push(product);
11     }
```

```
12    }
13
14    const end = performance.now();
15
16    if (results.length > 0) {
17      console.log("✅ Produkte gefunden:", JSON.stringify(results, null
18    } else {
19      console.log("❌ Keine Produkte gefunden");
20    }
21
22    console.log("⏱️  Zeit:", (end - start).toFixed(2), "ms");
23  }
24
25  filterProductsBy(p => parseInt(p.stock) < 10);
```

```

```

Und schon sind wir wieder bei $O(n)$! Key-Value ist fantastisch für exakte ID-Lookups, aber für Range-Queries oder Filter brauchen wir andere Paradigmen. Das ist der Trade-off!

> **Key Insight**: Key-Value ist kein Allheilmittel – es ist ein Werkzeug für einen spezifischen Use Case: **schneller Key-basierter Zugriff**.

Das Key-Value Prinzip: Formalisiert

Gut! Wir haben gesehen, dass Hash-basierte Indizes blitzschnell sind. Jetzt formalisieren wir das Ganze: Was genau ist ein Key-Value Store?

Definition

Ein Key-Value Store ist eine Datenstruktur, die:

- **Keys** (eindeutige Identifikatoren, meist Strings) auf **Values** (beliebige Daten) abbildet
- $O(1)$ **Lookup** garantiert (durchschnittlicher Fall)
- **Keine Struktur** für Values vorgibt (Blobs, JSON, Strings, …)
- **Kein Schema** erzwingt

Heute schauen wir uns an, wie professionelle Key-Value Stores wie Redis diese Prinzipien umsetzen – und welche zusätzlichen Features sie bieten.

Referenzen

Historische Entwicklung der Key-Value Stores

Bevor wir die technischen Details betrachten, lohnt sich ein Blick in die Geschichte: Wie entstand das Key-Value-Prinzip und warum ist es heute so wichtig?

Frühe Anfänge

- Schon in den 1960er/70er Jahren tauchten assoziative Arrays in Sprachen wie Lisp und Perl auf.
- Betriebssysteme nutzten Key-Value-Konzepte für Konfigurationsdateien und Registries.

Die Idee, Daten über eindeutige Schlüssel blitzschnell zu finden, ist also älter als die meisten modernen Datenbanksysteme.

Erste Datenbanksysteme & Web-Ära

- Mit Berkeley DB und später Memcached (Ende 1990er/2000er) wurde das Prinzip für Performance und horizontale Skalierung genutzt.
- Die Web-Ära brachte neue Herausforderungen: Millionen von Nutzern, Sessions, Caching – Key-Value Stores wurden zum Rückgrat vieler Webanwendungen.

Das CAP-Theorem (Consistency, Availability, Partition Tolerance) trieb die Entwicklung von verteilten Key-Value Stores wie DynamoDB und Redis voran.

Moderne Key-Value Stores

- Heute sind Redis, DynamoDB, RocksDB und LevelDB die Platzhirsche.
- Features wie TTL, atomare Operationen, Replikation und Sharding machen sie unverzichtbar für Cloud, Microservices und Echtzeit-Anwendungen.

Key-Value Stores sind nicht nur schnell, sondern auch extrem flexibel und skalierbar.

Der Zeitstrahl zeigt: Die Entwicklung verlief parallel zu den Anforderungen an Skalierbarkeit und Performance im Web.

Visualisierung: Key → Value Mapping

Das Grundprinzip ist denkbar einfach: Jeder Wert wird über einen eindeutigen Schlüssel gespeichert und abgerufen. Kein Schema, keine Tabellen, keine Joins – nur Schlüssel und Werte.

```
Key-Value Store
'user:42'       →  { name: 'Alice' , . . . }
'session:xyz'   →  { expires: 1700000000 }
'counter:views' → 12345
```

Der Clou: Der Zugriff erfolgt in konstanter Zeit – O von 1. Egal ob ihr 100 oder 100 Millionen Keys habt, der Lookup ist gleich schnell. Das ist die Superkraft von Key-Value Stores.

Grundoperationen

Operation	Beschreibung	Beispiel
`SET`	Wert speichern	`SET user:42 '{"name":"Alice"}'`
`GET`	Wert abrufen	`GET user:42`
`DELETE`	Wert löschen	`DELETE user:42`
`EXISTS`	Prüfen ob Key existiert	`EXISTS user:42`

Diese vier Operationen sind das Rückgrat jedes Key-Value Stores. Simpel, aber mächtig.

Redis in Action

Schauen wir uns das Ganze in Aktion an. Ich zeige euch echte Redis-Operationen, die ihr direkt im Browser ausführen könnt – ohne Server-Setup!

Redis Basics: SET & GET

```
const redis = new Redis();

// User-Daten speichern
await redis.set('user:42', JSON.stringify({
  name: "Alice",
  email: "alice@example.org"
}));

// Daten abrufen
const userData = await redis.get('user:42');
const user = JSON.parse(userData);

console.log('User Name:', user.name);
console.log('User Email:', user.email);

// Atomic Counter
await redis.set('page:views', '0');
await redis.incr('page:views');
await redis.incr('page:views');
await redis.incr('page:views');

const views = await redis.get('page:views');
console.log('Page Views:', views);
```

```
User Name: Alice
User Email: alice@example.org
Page Views: 3
User Name: Alice
User Email: alice@example.org
Page Views: 3
```

Redis ist der Klassiker: In-Memory, blitzschnell, mit optionaler Persistierung. Perfekt für Caching, Session Stores, Leaderboards. Hier läuft es direkt im Browser – probiert es aus!

Hash Operations: Strukturierte Objekte

```
const redis = new Redis();

// User als Hash speichern (effizienter!)
await redis.hset('user:1001', 'name', 'Bob');
```

```
4  await redis.hset('user:1001', 'name', 'Bob');
5  await redis.hset('user:1001', 'email', 'bob@example.org');
6  await redis.hset('user:1001', 'age', '28');
7  await redis.hset('user:1001', 'role', 'developer');
8
9  // Gesamtes Hash abrufen
10 const user = await redis.hgetall('user:1001');
11 console.log('User Object:', user);
12
13 // Einzelnes Feld abrufen
14 const name = await redis.hget('user:1001', 'name');
15 console.log('Name:', name);
16
17 // Feld existiert?
18 const hasPhone = await redis.hexists('user:1001', 'phone');
19 console.log('Has Phone:', hasPhone === 1);
```

```
User Object:
{"name":"Bob","email":"bob@example.org","age":"28","role":"developer"}
Name: Bob
Has Phone: false
User Object:
{"name":"Bob","email":"bob@example.org","age":"28","role":"developer"}
Name: Bob
Has Phone: false
```

Redis Hashes sind effizienter als JSON-Strings, wenn ihr nur einzelne Felder abrufen oder ändern wollt. Jedes Feld ist separat zugreifbar – perfekt für User-Profile!

TTL & Expiration: Selbstlöschende Daten

Eine der Killer-Features von Key-Value Stores: Time-To-Live oder TTL. Keys können automatisch ablaufen – perfekt für Sessions, Caches, Rate Limiting.

TTL in Action

```
1  const redis = new Redis();
2
3  // Session mit 10 Sekunden TTL
4  await redis.set('session:abc', JSON.stringify({ user_id: 42 }), 'EX',
5
6  // TTL abfragen
7  let ttl1 = await redis.ttl('session:abc');
8  console.log('TTL session:abc:', ttl1, 'seconds');
9
10 // Alternative: TTL nachträglich setzen
11 await redis.set('cache:data', 'cached_value');
12 await redis.expire('cache:data', 30);
13
14 let ttl2 = await redis.ttl('cache:data');
```

```
console.log('TTL cache:data:', ttl2, 'seconds');

// Key existiert?
const exists = await redis.exists('session:abc');
console.log('Session exists:', exists === 1);
```

```
TTL session:abc: 10 seconds
TTL cache:data: 30 seconds
Session exists: true
TTL session:abc: 10 seconds
TTL cache:data: 30 seconds
Session exists: true
```

Nach Ablauf der Zeit ist der Key einfach weg. Keine manuellen Cleanup-Jobs nötig – der Store kümmert sich selbst darum. In diesem Beispiel seht ihr, wie TTL funktioniert.

> **Use Case**: Session Store – nach 1 Stunde Inaktivität wird die Session automatisch gelöscht. Perfekt für Web-Apps!

Atomic Operations: Race Conditions vermeiden

Jetzt wird's interessant: Was passiert, wenn zwei Prozesse gleichzeitig denselben Counter hochzählen wollen?

Das Problem: Lost Update

```
// Simulation: Zwei "Prozesse" versuchen gleichzeitig zu inkrementier
const redis = new Redis();
await redis.set('counter', '10');

// Naiver Ansatz (UNSICHER!)
async function unsafeIncrement(processId) {
  const value = parseInt(await redis.get('counter'));
  const newValue = value + 1;
  await redis.set('counter', newValue.toString());

  console.debug(`Process ${processId} increments counter to:`, newVal

  return newValue;
}

// Beide "Prozesse" lesen denselben Wert (10)
console.log('Process 1 reads:', await redis.get('counter'));
console.log('Process 2 reads:', await redis.get('counter'));

// Beide schreiben 11 - ein Update geht verloren!
await Promise.all([unsafeIncrement(1), unsafeIncrement(2)]);
```

```
22
23 const final = await redis.get('counter');
24 console.log('Final value:', final, '(should be 12, but is 11!)');
```

```
Process 1 reads: 10
Process 2 reads: 10
Process 1 increments counter to: 11
Process 2 increments counter to: 11
Final value: 11 (should be 12, but is 11!)
Process 1 reads: 10
Process 2 reads: 10
Process 1 increments counter to: 11
Process 2 increments counter to: 11
Final value: 11 (should be 12, but is 11!)
```

Das ist eine klassische Race Condition: Beide lesen denselben Wert, beide schreiben denselben Wert plus 1 – ein Inkrement geht verloren. Lost Update!

Die Lösung: Atomic INCR

```
1  const redis = new Redis();
2  await redis.set('counter', '10');
3
4  // Atomares Inkrementieren (SICHER!)
5  const result1 = await redis.incr('counter');
6  console.log('After INCR #1:', result1);
7
8  const result2 = await redis.incr('counter');
9  console.log('After INCR #2:', result2);
10
11 const result3 = await redis.incr('counter');
12 console.log('After INCR #3:', result3);
13
14 // Auch mit INCRBY
15 await redis.incrby('counter', 5);
16 const final = await redis.get('counter');
17 console.log('After INCRBY 5:', final);
```

```
After INCR #1: 11
After INCR #2: 12
After INCR #3: 13
After INCRBY 5: 18
After INCR #1: 11
After INCR #2: 12
After INCR #3: 13
After INCRBY 5: 18
```

Redis garantiert: INCR ist atomar. Mehrere Prozesse können parallel inkrementieren, ohne dass Updates verloren gehen. Das ist die Magie atomarer Operationen!

Weitere atomare Operationen

Operation	Beschreibung
`INCR`	Atomares Inkrementieren um 1
`DECR`	Atomares Dekrementieren um 1
`INCRBY n`	Atomares Addieren von n
`DECRBY n`	Atomares Subtrahieren von n
`GETSET`	Setzen und alten Wert zurückgeben (atomar)
`SETNX`	Set if Not eXists (für Locking/Semaphoren)

Diese Operationen sind eure Waffen gegen Race Conditions. Nutzt sie!

Key-Design Patterns: Organisation ist alles

Keys sind nur Strings – aber wie organisiert man tausende oder Millionen Keys sinnvoll? Hier kommen Key-Design Patterns ins Spiel.

Pattern 1: Namespacing

```
user:42:profile
user:42:settings
user:42:sessions

product:99:details
product:99:reviews
product:99:inventory
```

Mit Doppelpunkten strukturieren wir Keys hierarchisch. Das ist nur eine Konvention, aber sie macht Keys lesbar und wartbar.

Pattern 2: Composite Keys

```
session:{user_id}:{timestamp}
cart:{session_id}:{product_id}
rate_limit:{ip}:{endpoint}:{minute}
```

Mehrere Dimensionen in einem Key – perfekt für komplexere Zugriffsszenarien.

Pattern 3: Leaderboard mit Sorted Sets

```
1  const redis = new Redis();
2
3  // Gaming Leaderboard erstellen
4  await redis.zadd('leaderboard', 9500, 'player:alice');
5  await redis.zadd('leaderboard', 8200, 'player:bob');
6  await redis.zadd('leaderboard', 12000, 'player:charlie');
7  await redis.zadd('leaderboard', 7800, 'player:diana');
8  await redis.zadd('leaderboard', 10500, 'player:eve');
9
10 // Top 3 Spieler (absteigend sortiert)
11 let topPlayers = await redis.zrevrange('leaderboard', 0, 2, 'WITHSCOR
12 console.log('🏆 Top 3 Players:');
13 for (let i = 0; i < topPlayers.length; i += 2) {
14   const rank = i / 2 + 1;
15   const player = topPlayers[i];
16   const score = topPlayers[i + 1];
17   console.log(`  ${rank}. ${player} - ${score} points`);
18 }
19
20 // Rang eines bestimmten Spielers
21 const aliceRank = await redis.zrevrank('leaderboard', 'player:alice')
22 console.log(`\nAlice's Rank: #${aliceRank + 1}`);
23
24 // Score erhöhen (atomar!)
25 await redis.zincrby('leaderboard', 500, 'player:alice');
26 const newScore = await redis.zscore('leaderboard', 'player:alice');
27 console.log(`Alice's new score: ${newScore}`);
```

```
🏆 Top 3 Players:
  1. player:charlie - 12000 points
  2. player:eve - 10500 points
  3. player:alice - 9500 points

Alice's Rank: #3
Alice's new score: 10000
🏆 Top 3 Players:
  1. player:charlie - 12000 points
  2. player:eve - 10500 points
  3. player:alice - 9500 points

Alice's Rank: #3
Alice's new score: 10000
```

Redis Sorted Sets sind perfekt für Ranglisten, Top-N Queries, Zeitreihen. Jedes Element hat einen Score, die Sortierung erfolgt automatisch. Ideal für Gaming, Analytics, Trending Topics!

Typische Use Cases

Wo KV glänzt

Jetzt wissen wir, WIE Key-Value funktioniert. Aber WANN sollten wir es einsetzen?

Use Case Matrix

Use Case	Warum KV?	Beispiel
Caching	$O(1)$ Lookup, TTL	Seiten-Cache, API-Responses
Session Store	Schneller Zugriff, Expiration	User Sessions, JWT
Rate Limiting	Atomic Counters, TTL	API Rate Limits (pro Minute)
Leaderboards	Sorted Sets	Gaming, Analytics
Feature Flags	Schneller Read, einfaches Update	A/B Tests, Rollouts

Überall dort, wo ihr schnellen Key-basierten Zugriff braucht und keine komplexen Queries, ist Key-Value ideal.

- Rate Limiting: Token Bucket Algorithm

Grenzen: Was KV NICHT kann

Kein Paradigma ist perfekt. Schauen wir uns an, wo Key-Value an seine Grenzen stößt.

Problem 1: Keine Range Queries

```
// Ich will alle User mit IDs zwischen 100 und 200
// ❌ Nicht möglich mit Standard Key-Value!

// Workaround: Alle Keys durchsuchen (teuer!)
KEYS user:*
```

Key-Value kennt nur exakte Lookups. Bereichsabfragen? Fehlanzeige. Dafür bräuchten wir Indexstrukturen – die hat KV nicht.

Problem 2: Keine Joins

```
// Ich will alle Bestellungen eines Users UND die Produktdetails
// ❌ Keine Joins in KV!

// Workaround: Mehrere GET Requests
GET user:42:orders    // → [99, 100, 101]
GET product:99
GET product:100
GET product:101
```

Jede Relation muss manuell aufgelöst werden. Bei komplexen Datenmodellen wird das schnell unübersichtlich.

Problem 3: Keine Ad-hoc Analysen

```
// "Zeige alle User, die in den letzten 7 Tagen aktiv waren"
// ❌ Ohne Secondary Indexes nicht möglich
```

Analytische Abfragen erfordern Strukturinformationen, die Key-Value nicht hat. Dafür brauchen wir Document, Column oder Relational Stores.

> **Trade-off**: KV ist simpel und schnell, aber unflexibel. Für komplexe Queries brauchen wir reichhaltigere Paradigmen.

Parallelisierung und Skalierung

Ein letzter Punkt: Wie skaliert Key-Value, wenn die Datenmengen wachsen? Key-Value Stores haben hier einen entscheidenden Vorteil: Sie sind von Natur aus horizontal skalierbar.

Sharding: Daten auf mehrere Knoten verteilen

Sharding bedeutet, dass wir unsere Keys auf mehrere Nodes verteilen. Jeder Node ist für einen bestimmten Key-Bereich verantwortlich.

Visualisierung: Hash-based Sharding

Mit Consistent Hashing berechnen wir aus jedem Key, auf welchem Node die Daten liegen. Das ermöglicht horizontale Skalierung: Mehr Nodes = mehr Kapazität!

Beispiel: Sharding in der Praxis

```javascript
// Simulation eines einfachen Sharding-Clients
class ShardedKeyValueClient {
  constructor(nodes) {
    this.nodes = nodes;  // Array von Node-IDs
  }

  // Consistent Hashing: Key → Node
  getNodeForKey(key) {
    let hash = 0;
    for (let i = 0; i < key.length; i++) {
      hash += key.charCodeAt(i);
    }
    const nodeIndex = hash % this.nodes.length;
    return this.nodes[nodeIndex];
  }

  // GET: Ermittle Node und hole Wert
  get(key) {
    const node = this.getNodeForKey(key);
    console.log(`GET "${key}" → routed to ${node}`);
    // In der Realität: HTTP Request an den Node
```

```
    return `[Value from ${node}]`;
  }

  // SET: Ermittle Node und speichere Wert
  set(key, value) {
    const node = this.getNodeForKey(key);
    console.log(`SET "${key}" → routed to ${node}`);
    // In der Realität: HTTP Request an den Node
    return `OK (stored on ${node})`;
  }
}

// Demo: 3 Nodes
const client = new ShardedKeyValueClient(['node-0', 'node-1', 'node-2

console.log('=== Sharding Demo ===\n');

// Verschiedene Keys werden auf unterschiedliche Nodes verteilt
client.set('user:42', '{"name":"Alice"}');
client.set('user:99', '{"name":"Bob"}');
client.set('product:123', '{"name":"Laptop"}');
client.set('session:abc', '{"user_id":42}');
client.set('cart:xyz', '{"items":[1,2,3]}');

console.log('\n--- Retrieving Data ---\n');

client.get('user:42');
client.get('product:123');
client.get('session:abc');

console.log('\n💡 Jeder Key landet auf einem bestimmten Node!');
console.log('   → Mehr Nodes = mehr Parallelität und Kapazität');
```

```
=== Sharding Demo ===

SET "user:42" → routed to node-1
SET "user:99" → routed to node-1
SET "product:123" → routed to node-2
SET "session:abc" → routed to node-2
SET "cart:xyz" → routed to node-1

--- Retrieving Data ---

GET "user:42" → routed to node-1
GET "product:123" → routed to node-2
GET "session:abc" → routed to node-2

💡 Jeder Key landet auf einem bestimmten Node!
   → Mehr Nodes = mehr Parallelität und Kapazität
```

Seht ihr? Jeder Key wird automatisch einem Node zugeordnet. Das System skaliert linear: 3 Nodes können 3x so viele Requests parallel verarbeiten wie 1 Node!

Replication: Ausfallsicherheit durch Redundanz

Sharding allein reicht nicht – was passiert, wenn ein Node ausfällt? Hier kommt Replication ins Spiel.

Master-Replica Architektur

Schreiboperationen gehen an den Master, der dann asynchron an Replicas repliziert. Lesezugriffe können vom Master oder von beliebigen Replicas bedient werden – das verteilt die Last!

Trade-offs bei Replication

Replikations-Typ	Konsistenz	Performance	Use Case
Synchron	✅ Stark	⚠️ Langsam	Finanztransaktionen
Asynchron	⚠️ Eventual	✅ Schnell	Social Media Feeds, Caching
Semi-Synchron	🟡 Mittel	🟡 Mittel	E-Commerce, Session Stores

Der Klassiker: Konsistenz vs. Performance. Für Session Stores ist Eventual Consistency meist ok – für Banküberweisungen nicht!

Redis Enterprise & CRDTs

Jetzt wird's spannend: Redis Enterprise nutzt **CRDTs** (Conflict-free Replicated Data Types) für Multi-Master-Replication ohne Konflikte!

Was sind CRDTs?

CRDTs sind Datenstrukturen, die **garantiert konfliktfrei** zusammengeführt werden können, selbst wenn mehrere Replicas gleichzeitig Updates erhalten.

Beispiel: Counter-CRDT

```
// Klassisches Problem: Zwei Replicas inkrementieren gleichzeitig
// Replica 1: counter = 10 → 11
// Replica 2: counter = 10 → 11
// Merge: Was ist das Ergebnis? 11? 12? ❌ Konflikt!

// CRDT-Lösung: G-Counter (Grow-only Counter)
class GCounter {
  constructor(replicaId) {
    this.replicaId = replicaId;
    this.counters = {};  // Pro Replica ein eigener Counter
  }

  increment() {
    if (!this.counters[this.replicaId]) {
      this.counters[this.replicaId] = 0;
    }
    this.counters[this.replicaId]++;
    console.log(`Replica ${this.replicaId}: local counter = ${this
      .counters[this.replicaId]}`);
  }

  value() {
    // Gesamtwert: Summe aller Replica-Counter
    return Object.values(this.counters).reduce((sum, val) => sum + va
  }

  merge(other) {
    // Merge: Maximum pro Replica nehmen
    for (const [replica, count] of Object.entries(other.counters)) {
      if (!this.counters[replica] || this.counters[replica] < count)
        this.counters[replica] = count;
      }
    }
    console.log(`Merged: total = ${this.value()}`);
  }
}

// Simulation: Zwei Replicas inkrementieren unabhängig
console.log('=== CRDT Counter Demo ===\n');

const replica1 = new GCounter('replica-1');
const replica2 = new GCounter('replica-2');

replica1.increment();  // replica-1: 1
replica1.increment();  // replica-1: 2
```

```
replica2.increment();  // replica-2: 1
replica2.increment();  // replica-2: 2
replica2.increment();  // replica-2: 3

console.log('\nBefore merge:');
console.log(`  Replica 1 sees: ${replica1.value()}`);
console.log(`  Replica 2 sees: ${replica2.value()}`);

console.log('\nMerging Replica 2 → Replica 1:');
replica1.merge(replica2);

console.log('\nAfter merge:');
console.log(`  Total: ${replica1.value()} ✅ (2 + 3 = 5, kein Verlust
```

```
=== CRDT Counter Demo ===

Replica replica-1: local counter = 1
Replica replica-1: local counter = 2
Replica replica-2: local counter = 1
Replica replica-2: local counter = 2
Replica replica-2: local counter = 3

Before merge:
  Replica 1 sees: 2
  Replica 2 sees: 3

Merging Replica 2 → Replica 1:
Merged: total = 5

After merge:
  Total: 5 ✅ (2 + 3 = 5, kein Verlust!)
```

CRDTs lösen das Problem mathematisch: Jede Replica hat ihren eigenen Counter. Beim Merge nehmen wir das Maximum – garantiert konfliktfrei! Redis Enterprise nutzt dies für Active-Active Geo-Replication.

Redis Enterprise: Active-Active mit CRDTs

Mit Redis Enterprise könnt ihr weltweit verteilte Master-Nodes haben, die alle Writes akzeptieren. CRDTs garantieren, dass alle Replicas konfliktfrei konvergieren – ohne manuelle Konfliktauflösung!

CRDT-Typen in Redis Enterprise

CRDT-Typ	Operationen	Use Case
Counter	INCR, DECR	Page Views, Likes
Register	SET (Last-Write-Wins)	User Status, Config
Set	SADD, SREM	Tags, Permissions
Sorted Set	ZADD (max score wins)	Leaderboards
Hash	HSET (per-field LWW)	User Profiles

Redis Enterprise unterstützt verschiedene CRDT-Typen out-of-the-box. Ihr schreibt normalen Redis-Code, das System kümmert sich um Konfliktauflösung!

Herausforderungen bei Skalierung

Trotz aller Vorteile gibt es Herausforderungen:

Die Realität

- **Konsistenz**: Bei verteilten Systemen schwieriger zu gewährleisten
  - CAP-Theorem: Consistency, Availability, Partition Tolerance – pick two!
  - Eventual Consistency ist oft ein Kompromiss
- **Netzwerk-Latenz**: Mehr Nodes = mehr Kommunikation
  - Cross-Region Replication: 100+ ms Latenz
  - Lösung: Geo-Partitioning, lokale Caches
- **Rebalancing**: Bei Änderungen in der Datenverteilung aufwendig
  - Neuer Node hinzufügen? → Keys müssen umverteilt werden
  - Consistent Hashing minimiert Umverteilung (nur ~1/n der Keys bewegen sich)

Verteilte Systeme sind komplex! Redis Enterprise und ähnliche Lösungen nehmen euch viel Arbeit ab, aber das Verständnis der Trade-offs bleibt essentiell.

> **Best Practice**: Startet einfach (Single Node), skaliert bei Bedarf horizontal. Premature Optimization ist die Wurzel allen Übels!

Zusammenfassung & Wrap-up

Fassen wir zusammen: Key-Value Stores sind das Schweizer Taschenmesser für schnelle, strukturierte Zugriffe. Simpel, robust, blitzschnell.

Key Takeaways

- ✅ $O(1)$ **Lookup**: Konstante Zugriffszeit, egal bei welcher Datenmenge
- ✅ **TTL & Expiration**: Selbstlöschende Daten für Sessions, Caches
- ✅ **Atomare Operationen**: Race Conditions vermeiden mit `INCR`, `SETNX`
- ✅ **Key-Design Patterns**: Namespacing, Composite Keys, Sorted Sets
- ✅ **Replikation**: Daten werden auf mehrere Knoten verteilt (Master-Replica, semi-synchron, asynchron) für Ausfallsicherheit und Skalierung
- ✅ **Partitionierung (Sharding)**: Daten werden logisch oder technisch aufgeteilt, um große Datenmengen und viele Zugriffe zu bewältigen
- ✅ **Konsistenzmodelle**: Von starker Konsistenz (alle sehen immer den aktuellen Stand) bis zu eventual consistency (Daten gleichen sich zeitverzögert ab)
- ❌ **Keine Range Queries**: Nur exakte Lookups möglich
- ❌ **Keine Joins**: Relationen manuell auflösen
- ❌ **Keine Ad-hoc Analysen**: Strukturinformationen fehlen

Key-Value ist perfekt für Caching, Sessions, Rate Limiting – überall dort, wo Geschwindigkeit und Einfachheit zählen. Für komplexere Datenmodelle schauen wir uns in den nächsten Sessions Document und Column Stores an.

Interaktives Redis-Terminal

```
// Redis Playground: Experimentiert selbst!
redis = new Redis();

// Initial Setup
await redis.set('counter', '0');
await redis.hset('user:demo', 'name', 'Demo User');
await redis.zadd('scores', 100, 'Alice');

console.log('🎮 Redis Playground Ready!\n');
console.log('Try these commands:');
console.log('  await redis.incr("counter")');
console.log('  await redis.get("counter")');
console.log('  await redis.hgetall("user:demo")');
console.log('  await redis.zadd("scores", 200, "Bob")');
console.log('  await redis.zrevrange("scores", 0, -1, "WITHSCORES")')
console.log('  await redis.keys("*")');
```

Nutzt das Terminal, um selbst zu experimentieren! Probiert verschiedene Befehle aus, baut eigene Use Cases – Learning by Doing!
